Docstrings and Function `help`

Built-in function `help` displays the docstring from a function definition. For example, consider this function:

```
def area(base, height):
    """(number, number) -> number

    Return the area of a triangle with dimensions base
    and height.
    """

    return base * height / 2
```
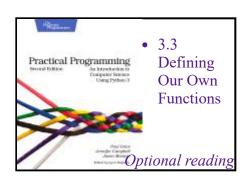

Calling `help` on function `area` produces this output:

```
>>> help(area)
Help on function area in module __main__:

area(base, height)
    (number, number) -> number

    Return the area of a triangle with dimensions base
    and height.
```
